Review of Conscious Sedation

G Neyman

Citation

Abstract

Conscious sedation can be a very valuable tool in the armamentarium of the physician practicing in the emergency setting. Several studies have shown that it is (probably) underutilized. When asked why, the most common response was "lack of training (for both the physician and other personnel)." This article will review some of the clinical issues regarding conscious sedation.

DEFINITION

Intravenous Conscious Sedation (IVCS) is a minimally depressed level of consciousness that retains the patient's ability to maintain a patent airway independently and continuously and respond appropriately to physical stimulation and verbal commands. IVCS may be administered during therapeutic, diagnostic or surgical procedures. The drugs, dosages and techniques utilized for IVCS are not intended to produce loss of consciousness. Conscious sedation should be distinguished from two other levels of consciousness: deep sedation and general anesthesia. Deep sedation is a controlled state of depressed consciousness or unconsciousness from which the patient is not easily aroused, accompanied by a partial or complete loss of protective reflexes, including the ability to maintain a patent airway independently and respond purposefully to physical stimulation or verbal command. General anesthesia is a controlled state of unconsciousness accompanied by a loss of protective reflexes, including loss of the ability to maintain a patent airway or to respond purposefully to physical stimulation or verbal command.

In actuality, a continuum exists among conscious sedation, deep sedation and general anesthesia. The patient's age and preexisting medical conditions may significantly alter the dosing requirements needed for IVCS. If either deep sedation or general anesthesia is required for the procedure, skilled anesthesia personnel should be available to assist in the management of the patient.

PERSONNEL AND TRAINING

The recommended minimum number of personnel involved in the care of patients undergoing IVCS during the entire procedure should be two: (1) the physician who performs the diagnostic, therapeutic or surgical procedure; and (2) the individual (M.D., R.N., P.A. or R.T.) who monitors the patient and his/her response to both the sedation and the procedure and who is capable of assisting with any supportive or resuscitative measures. One of these two personnel must be available to the patient from the time the procedure has been completed until the time the patient has adequately recovered or has been turned over to personnel performing recovery care. The individual who monitors the patient should have no other significant responsibilities, i.e., no tasks or duties which would compromise his/her ability to monitor the patient. In certain circumstances, e.g., when the patient has been identified as “high risk” or when the procedure to be carried out is particularly complex, a third individual or member of the anesthesia care team should be present to assist with the procedure.

Educational and credentialing mechanisms for IVCS should be part of the usual institutional procedures and should function through any department that has staff undertaking IVCS. These mechanisms should include a process for evaluating and documenting an individual's demonstration of the knowledge, skills and abilities related to the management of patients receiving IVCS. The direct training of staff involved in IVCS should take place either at the departmental level or at the institutional level with specific departmental input. Courses regarding IVCS, developed with input from anesthesiologists, should be available.
in accord with the IVCS policy. Individuals who administer IVCS should be competent in airway management and resuscitation measures (i.e., at least BLS certified; ACLS certified suggested) and should be educated regarding and demonstrate knowledge in the use, side effects and complications of the medication to be given. The individual responsible for monitoring the patient should have the aforementioned skills and should also have knowledge and experience in the use of oximetry and, when applicable, cardiac monitoring equipment and in the recognition of cardiac arrhythmias.

LOCATION/EQUIPMENT/MONITORING
The room where the procedure utilizing IVCS is scheduled to take place should have adequate, uncluttered floor space (to accommodate emergencies) and be equipped with:

- a source and means for providing supplemental oxygen;
- an airway and a self inflating positive-pressure oxygen delivery system capable of delivering 100% oxygen at a 15 liter/minute flow rate for at least 60 minutes. Various bag and mask sizes should be available in those circumstances where appropriate;
- a source of suction (portable or wall);
- a pulse oximeter with alarm;
- a device for taking blood pressure (manual or automatic);
- a cardiac monitor with alarm: recommended for patients with an ASA classification of III or greater or with a history of cardio-pulmonary disease; and
- a specific pharmacological reversal agent for the type of sedation to be used.

An emergency cart should be immediately accessible to the room where the procedure is to take place. Means for notifying emergency support services such as respiratory therapy and code pages should be clearly identified and posted in the IVCS location.

PRIOR TO PROCEDURE
It should be ascertained that:

- the patient's state of consciousness and medical condition are appropriate for the use of conscious sedation;
- the patient's American Society of Anesthesiologist's Physical Status Classification (ASA) is determined (see table 1);
- preparatory studies appropriate to the procedure and patient have been done;
- there is a sedation order given by the physician who will perform the procedure, unless that physician will be administering the medication him/herself;
- the patient has no allergy or sensitivity to the prescribed medication (see Table 2 for medication examples);
- the patient's pertinent medical history, including current drug regimen, has been obtained/reviewed;
- the patient has been NPO for at least six hours prior to the planned procedure, except for clear liquids which may be given up to two hours before the procedure. Medications may be administered with a sip of water. In cases of emergencies, where the patient has not been NPO, IVCS may be dangerous. It should either not be administered or administered judiciously to avoid unconsciousness or suppression of protective airway reflexes.
- informed consent has been obtained. The patient/guardian must be informed of the risks and alternatives to IVCS; documentation must be in the medical record prior to procedure;
- a physical exam has been conducted which includes assessing/measuring the patient's:
  - estimated weight,
  - vital signs (baseline blood pressure; heart rate; respiratory rate, pattern and quality),
  - baseline oxygen saturation,
  - airway (i.e., an evaluation performed in anticipation of possible intubation, e.g., checking condition of teeth; range of neck motion; ability to open mouth),
○ chest and cardiac status,
○ general neurologic status (e.g., assessing mental status; presence or absence of stroke deficits), and
○ physical status (e.g., ASA physical status category);

- the patient has a functioning IV line or heparin lock;
- the patient’s oxygen requirements are evaluated. The need for administration of supplemental oxygen should be considered. Patients who are over the age of 60 or who have a medical history significant for heart, lung or kidney disease should be routinely given supplemental oxygen unless specifically contraindicated; and
- the patient has been instructed to report any problems associated with the procedure or the IVCS (e.g., pain, difficulty in breathing) to the individual responsible for monitoring the patient.

If any difficulty with the patient or procedure is anticipated, appropriate medical consultation should be obtained.

Table 1: American Society of Anesthesiologists Physical Status Classification

Class I
There is no organic, physiological, biochemical or psychiatric disturbance. The pathologic process for which operation is to be performed is localized and is not a systemic disturbance.

Class II
Mild to moderate systemic disturbance caused either by the condition to be treated surgically or by other pathophysiological processes.

Class III
Severe systemic disturbance or disease from whatever cause, even though it may not be possible to define the degree of disability with finality.

Class IV
Indicative of the patient with severe systemic disorder already life-threatening, not always correctable by the operative procedure.

Class V
The moribund patient who has little chance of survival but is submitted to operation in desperation.

Procedures,” Risk Management Committee, Departments of
Anesthesia, Harvard Medical School, Boston, MA.

DURING THE PROCEDURE
The individual responsible for monitoring the patient should
ascertain and record:

- all medication administered (route, site, time, drug,
dose);
- the amount and means of oxygen administered;
- the patient’s vital signs (blood pressure, respiratory
rate and quality, heart rate, and level of
responsiveness) every 5 - 10 minutes. If the patient
has been classified ASA III or greater or has a
history of cardio-pulmonary disease, the heart rate
and rhythm should be displayed continuously by
cardiac monitor; and
- the patient’s oxygen saturation (which is displayed
continuously by pulse oximeter) every 5 - 10
minutes.

The patient’s head position should be checked frequently to
ensure a patent airway. If the patient becomes unstable
during the procedure, appropriate medical consultation
should be sought immediately.

FOLLOWING THE PROCEDURE
The individual whose responsibility it is to monitor the
patient should ascertain and record the patient’s vital signs
(as defined directly above) every 5 - 10 minutes for a
minimum of 30 minutes following the last administered dose
of IV sedation. Beyond this 30 minute period and, if stable,
vital signs should be recorded every 15 minutes until the
patient returns to his/her pre-procedure state. Oxygen
saturation levels should be obtained if indicated. The patient
must be observed for a minimum of 30 minutes following
the procedure.

Discharge criteria should include:

- patient has stable vital signs and oxygen saturation
level;
- patient’s swallow, cough and gag reflexes are
present, or appropriate to baseline;
- patient is alert or appropriate to baseline;
- patient can sit unaided if appropriate to baseline
and procedure;
- patient can walk with assistance if appropriate to
baseline and procedure;
- nausea and dizziness are minimal;
- hydration is adequate;
- dressing/procedure site have been checked if
applicable; and
- discharge order has been written by physician. An
R.N. may discharge the patient utilizing
appropriate criteria based upon a prior discharge
order.

If the procedure was done on an outpatient or ambulatory
care basis, the patient should be given: (1) written
instructions that include an explanation of potential or
anticipated limitations on activities, behavior and diet; and
(2) a 24-hour emergency contact prior to discharge.
Ambulatory care patients should not leave the premises
unless they are under the care of a competent adult; they
should be advised to refrain from operating heavy
machinery, driving a care, consuming alcohol and making
important decisions for 12 to 24 hours.

CONCLUSION

Conscious sedation is an excellent way to perform
diagnostic, therapeutic and/or surgical procedures with
comfort to the patient. Adequate training, preparation and
ultimately experience will allow the physician working in
the emergency setting to utilize the valuable tool.
