Citation

Abstract
Recurrent aphthous stomatitis (RAS) is one of the most common oral mucosal lesions seen in primary care. Over the past four years we have treated 15 RAS patients with vitamin B12. Of these, 11 patients reported a rapid and complete recovery from RAS during treatment and the other four reported pronounced reduction in the frequency and severity of RAS episodes. We suppose that a treatment with vitamin B12 can be effective for patients suffering from RAS any origin, regardless of their serum vitamin B12 level. Now we are doing double-blind, placebo-controlled, randomized clinical trial addressing the issue. It's supposed to confirm the safety and effectiveness of vitamin B12 therapy for RAS.

INTRODUCTION
Recurrent aphthous stomatitis (RAS) is one of the most common oral mucosal lesions seen in primary care. The Greek term “aphthai” was initially used in relation to disorders of the mouth and is credited to Hippocrates. RAS is a pathologic condition characterized by recurring, painful, small, oral mucosal ulcers with a round or oval aspect, clean borders, a peripheral erythematous halo, and a yellow or grayish base. The frequency of aphthous ulcers is up to 25% in the general population, and three-month recurrence rates are as high as 50%. RAS is an idiopathic condition in most patients. The most likely precipitating factors are local trauma and stress. Other associated factors include systemic diseases, nutritional deficiencies, food allergies, genetic predisposition, immune disorders, medications, and HIV infection. Although RAS may be a marker of an underlying systemic illness such as celiac disease, or may present as one of the features of Behcet's disease, in most cases no other body systems are affected, and patients remain otherwise fit and well. Since the etiology is unknown, diagnosis is entirely based on history and clinical criteria and no laboratory procedures exist to confirm the diagnosis. Herbal multivitamins, adhesive pastes, local antiseptics, local antibiotics, topical non-steroidal anti-inflammatory drugs, topical corticosteroids, and even topical and systemic immuno-modulators, immunosuppressants, and corticosteroids are among the treatments given to RAS patients. Most of these achieve “short term” therapeutic goals such as alleviation of pain, reduction of ulcer duration, and recovery of normal oral function. Very few treatments have been reported to achieve “long term” therapeutic goals such as reduction of the frequency and severity of RAS and maintenance of remission. We previously reported the successful treatment of three RAS patients with intramuscular vitamin B12 injections (IM). Now we have treated 15 RAS patients with vitamin B12. We present a review of our clinical experience. We believe that the results are promising and that this therapeutic option should be further explored.

METHODS
Fifteen patients suffering from RAS have been treated with vitamin B12 in our clinics over the past four years. In most cases they have presented to the clinic with unrelated symptoms, and the oral ulcers were incidental findings on physical examination. Patients were asked whether oral ulcers were a recurring problem. Before initiating vitamin B12 therapy a complete blood count was done and plasma vitamin B12 and folic acid levels were assessed. We used one of two therapeutic regimens:

1. IM injections of vitamin B12 (1000 mcg weekly for the first month and then 1000 mcg monthly – as maintenance therapy) for patients with serum vitamin B12 level below 100 pg/ml, for patients with peripheral neuropathy or macrocytic anemia, and for patients coming from a low socio-economic level (in our country IM vitamin B12 treatment is cheaper than oral vitamin B12).
Successful treatment of recurrent aphthous stomatitis of any origin with vitamin B12 (irrespective of its blood level)

One sublingual vitamin B₁₂ tablet (1000 mcg) per day.

No other treatment was given for RAS throughout the treatment and follow-up periods. The follow-up period ranged from 3 months to 4 years.

RESULTS

This report presents the results of treatment for 15 patients from two primary care practices. Nine patients (60%) were males. The mean age was 38.7±18.8 years (range 15-86). The patient population was ethnically heterogenic with 8 Jewish and 7 Bedouin patients. The mean duration of RAS prior to vitamin B₁₂ therapy was 11.2±10.7 years (range 1-38). The results of blood tests prior to therapy are shown in Table 1.

Eleven of the 15 patients (73%) were treated by IM injection, in most cases due to socio-economic considerations. The main results of treatment are presented in Table 2 and Fig. 1. Eleven patients reported a rapid and complete recovery from RAS during treatment and the other four reported pronounced reduction in the frequency and severity of RAS episodes. Two of the four patients who did not report complete recovery were treated with sublingual vitamin B₁₂. The other two patients, who were treated with IM vitamin B₁₂, had long periods of non-adherence (over 2 months). When these two non-adherent patients received regular IM injections their aphthous ulcers disappeared completely.

DISCUSSION

In this report we review our clinic experience with 15 patients treated with vitamin B₁₂ for RAS. Interestingly, none of the patients complained of oral ulcers; all cases were discovered on physical examination. Reviewing literature, we were amazed by statistics that 10 to 50% of the general population suffers from RAS, and up to 60% of the medical staff! Why were we surprised? RAS is not considered a reason to pay a visit to the primary physician. Patients rarely complain of RAS, except for how it influences their daily lives. When we started to elucidate the phenomenon, we understood that at some moment aphthae in one’s mouth was accepted as “a part of life”. Many affected patients may not seek medical help because they don’t believe that there is a definitive solution to their problem. Therefore, primary care physicians should actively inquire about this problem.

Although the precise role of vitamin B₁₂ deficiency in the pathogenesis of RAS is unclear, suppression of cell-mediated immunity and changes in the cells of the tongue and buccal mucosa have been reported. In terms of the normal range of vitamin B₁₂ levels, only two patients in our patient population had vitamin B₁₂ deficiency (below 125 pg/ml), three others had marginal levels (from 125 to 250 pg/ml) and the other 10 had normal levels (above 250 pg/ml). There was no difference in the outcome of treatment between patients with deficient or borderline levels vitamin B₁₂ levels, and those with a normal level. How can this
phenomenon be explained? In most likelihood, a serum vitamin B\textsubscript{12} level may not reliably indicate “functional” vitamin B\textsubscript{12} status. The test for B\textsubscript{12} has several pitfalls.\textsuperscript{22} Most laboratories set normal limits at 200 to 900 pg/mL, but sensitivity and specificity vary greatly, depending on the method used. False negatives (ie, elevated levels in the presence of deficiency) can occur in true deficiency, active liver disease, lymphoma, autoimmune disease, and myeloproliferative disorders. False positives (ie, low levels in the absence of deficiency) can occur in folic deficiency, pregnancy, multiple myeloma, and excessive vitamin C intake. The measurements are quite accurate for serum vitamin B\textsubscript{12} levels below 100 pg/mL. Some authors have suggested that vitamin B\textsubscript{12} treatment should be offered to all patients with clinical appearances of vitamin B\textsubscript{12} deficiency, even if their serum vitamin B\textsubscript{12} level is normal.\textsuperscript{22} Another explanation for this phenomenon (our “working hypothesis”) is that vitamin B\textsubscript{12} has some unique, but still unrecognized functions. Multifunctional systems have to maintain homeostasis. Man is an ideal example of a system that constantly aspires to attain optimal regulation, even under the stress of severe pathology. We assume that there are universal, interchangeable (as required) biologically active substances that regulate the system and try to keep it in balance. We propose that one of these substances is vitamin B\textsubscript{12}. Why vitamin B\textsubscript{12}? The list of organs and body systems in which vitamin B\textsubscript{12} plays a functional role is constantly being added to. Vitamin B\textsubscript{12} affects the normal growth of children, the peripheral and central nervous systems, bone marrow, skin and mucous membranes, bones, and vessels. Vitamin B\textsubscript{12} (cobalamin) is unique among all the vitamins in that it contains not only a complex organic molecule but also an essential trace element, cobalt. Vitamin B\textsubscript{12} plays an important role in DNA synthesis and has important immunomodulatory and neurotrophic effects. Deficiency of vitamin B\textsubscript{12} can lead to a wide spectrum of disorders that can often be reversed by early diagnosis and prompt treatment.

It is possible that even when the serum cobalamin level is high, treatment with vitamin B\textsubscript{12} can correct defects caused by other biologically active substances. We suppose this has been proved successful in the treatment of recurrent aphthous stomatitis with vitamin B\textsubscript{12} (irrespective of its blood level). We call this phenomenon the “Master Key” effect.\textsuperscript{23}

**CONCLUSION**

Treatment with vitamin B\textsubscript{12} can be effective for patients suffering from RAS any origin, regardless of their serum vitamin B\textsubscript{12} level. Now we are doing double-blind, placebo-controlled, randomized clinical trial addressing the issue. It’s supposed to confirm the safety and effectiveness of vitamin B\textsubscript{12} therapy for RAS.
