Abstract

About 1% of live born children have congenital heart defects. In this study we present a case with patent ductus arteriosus and coarctation of aorta where aberrant right subclavian artery originates from the coarcted segment and our successful surgical approach.

INTRODUCTION

The first successful surgical repair of CoAo was performed in 1944 (1). The field of pediatric cardiac interventions has witnessed a dramatic increase (2).

CASE PRESENTATION

Our case was a 2-year-old girl who was referred to our Pediatric Cardiology Unit after revealing a cardiac murmur during a physical examination following a fall from a chair 6 months ago. Her transthoracic echocardiography (TTE) showed patent ductus arteriosus (PDA), bicuspid aorta, coarctation of aorta (CoAo) and aortic arch anomalies. She was then prepared for cardiac catheterization. This procedure confirmed the diagnosis put via TTE. An additional finding was an aberrant right subclavian artery originating from the coarcted segment (RSCa)(Figure 1).

Figure 1

Figure 1. Angiographic view showing the right subclavian artery originating from the coarcted segment

Our case was then taken to the operating room. At first, her PDA was ligated. Then, the coarcted segment was resected (Figures 2&3).

Figure 2

Figure 2. View of the coarcted segment and elements of the aortic arch after ligation of the PDA

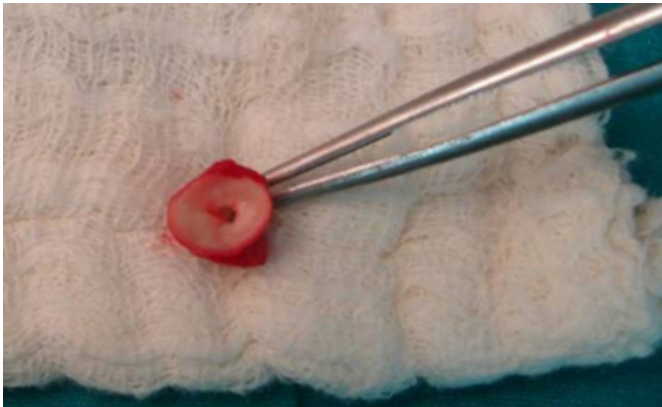

Figure 3

Figure 3. Extirpated coarcted segment

Afterwards, aortic arch and descending aorta were anastomosed in an end-to-end fashion. RSCa was then translocated and end-to-side anastomosed to the left subclavian artery (Figure 4).

Figure 4

Figure 4. Translocation of the right subclavian artery onto the left subclavian artery

During this procedure, right upper extremity pulses were monitored by sonic Doppler while continuously monitoring the viability of the extremity with pulse oximetry. The post-operative course was uneventful with successful correction. Postoperative echocardiographic data confirmed that coarctation gradient decreased from 26 to 6 mmHg after surgical correction and complete occlusion of the ductus arteriosus was achieved without any complication.

DISCUSSION

In the study of Liu et al, most of the coarctation is complicated by PDA; 49% of their patients were complicated with PDA (3). Echocardiography is the first choice in the diagnosis of CoAo; however, angiography is still necessary in some cases. The outcome of the surgical correction is good and the majority of the patients have no symptoms (4).
