Abstract
Primary renal cell synovial sarcoma is a rare entity and less than 30 cases are reported in literature. We report a case of 35-year-old male with primary synovial sarcoma of kidney, which was confirmed by SYT-SSX translocation.

CASE REPORT
A 35-year-old male presented with sudden onset right flank pain with haematuria. He was a non-smoker with unremarkable past medical and family history. He was afebrile with tenderness in the right lumbar region. Urine dip was positive for blood and protein and abdominal X-ray was inconclusive.

A CT of the abdomen showed a large heterogeneous well defined mass measuring 15.4x13.8x9.5 cm. with cystic and solid components arising from the right kidney and centred around the renal hilum with antero-posterior extension abutting the psoas posteriorly (Fig.1).

Figure 1

Mild hydronephrosis involving the upper and lower poles was seen due to mass effect but no invasive feature. There was no lymphadenopathy or intra abdominal metastasis.

The patient was operated and a large cystic kidney was found for which a nephrectomy was performed. The cyst was ruptured during operation.

Macroscopically, the specimens weighed 979 g and the largest specimen measured 15x10x7.5 cm. It was largely occupied by partially solid and partially cystic lesion with haemorrhagic and shiny grey solid content.

Microscopically, the tumour showed the presence of monomorphic spindle cell proliferation growing in short intersecting fascicles or in solid sheets with high mitotic activity. The tumour also showed cysts of variable size lined by inactive polygonal eosinophilic cells with apically located nuclei (hobnail appearance). (Fig. 2, 3, 4)

Figure 2
Case Report: Primary Synovial Sarcoma of Kidney

Immunohisto-chemistry showed tumour cells to be positive for Vimentin, BCL2 and CD99. Tumour cells were negative with Desmin, SMA, S100, CK, CD31, Factor8, Melan A, CD117, LCA, EMA, HMCK, CD10 and MyoD1. These appearances were in keeping with biphasic synovial sarcoma with focal high grade areas.

Cytogenetic analysis later confirmed the diagnosis of synovial sarcoma. RT-PCR analysis showed SYT/SSX translocation, a characteristic feature of the condition.

The patient is currently being treated with VIDE (Vincristine, Ifosfamide, Doxorubicin and Etoposide) chemotherapy.

DISCUSSION
Sarcomas originating in kidneys of adults are rare. Lieomyosarcoma is the most common renal sarcoma, which accounts for 40-60% followed by rhabdomyosarcoma, angiosarcoma, haemangiopericytoma, liposarcoma, chondrosarcoma and osteosarcoma. Primary renal sarcoma in childhood is mainly confined to clear cell sarcoma of kidney and malignant rhabdoid tumour. Synovial sarcoma is the fourth most common sarcoma, which accounts for 5-10% of all soft tissue sarcoma cases. Synovial sarcoma primarily occurs in extremities of young adult but has been reported in variety of unusual locations in which there is no synovial structure as detailed in Table 1.

Primary renal synovial sarcoma is extremely rare and was first described by Faria et al in 1999. It has been reported in the age group between 19-61. A M:F ratio of 1.7:1 has been established from review of first 19 cases. Patients presented with either flank pain or haematuria or both. The tumours at the time of diagnosis ranged from 5-19 cm with 67% having grossly identifiable cyst and 82% having cyst on microscopy. Histologically, tumours are typically mitotically active with monomorphous plump spindle cells and indistinct cell borders growing in short, intersecting fascicles or in solid sheets. Cysts are lined by mitotically inactive polygonal eosinophilic cells with apically located nuclei (“hobnailed epithelium”), and appear to be entrapped native renal tubules, which may be extensively dilated. Areas of solid aggregation or fascicles of the tumour cells alternating with hypocellular myxoid tissues, together with areas displaying a prominent haemangiopericytoma-like pattern, may be found. Histologically, the tumour is classified as Monophasic, Biphasic (epithelial cells and
spindle cells) and Poorly differentiated.
Immunohistochemical markers are helpful in differential
diagnosis of spindle cell neoplasm. However, none of these
markers so far available is specific enough to make the
diagnosis of Synovial Sarcoma (7). Table 2 details the
immunohistochemistry of synovial sarcoma

Despite the Histopathology and Immunohistochemistry
differentiating between synovial sarcoma and congenital
mesoblastic nephroma or clear cell sarcoma can be difficult.
Cytogenetics, Chromosomal study and Molecular analysis
has greatly aided in diagnosis of Synovial sarcoma. A
characteristic translocation t(X;18) is found in 90% of the
patients of synovial sarcoma (7). Crew et al demonstrated
that the t(X;18)(p11.2;q11.2) results in the fusion of
chromosome 18 SYT gene to either of the two homologous
genes SSX1 or SSX2 (7). The prognosis of patients with SYT-
SSX2 translocation is better than SYT-SSX1 translocation
(8).

The treatment of primary renal synovial sarcoma involves
surgery and adjuvant chemotherapy. Synovial sarcomas are
chemosensitive to ifosfamide and doxorubicin based
chemotherapy with a response rate of 24% (9). The prognosis
despite treatment is poor with a 5-year survival rate of
synovial sarcoma being 42-89% (9). Factors predicting worse

prognosis for patients with synovial sarcoma include tumour
size (>5cm), male gender, older age (>20 years), extensive
tumour necrosis, high grade, large number of mitotic figures
(>10 per 10 high powered fields), neurovascular invasion
and, recently, the SYT-SSX1 variant (10).
