Abstract

OBJECTIVE(S):
To assess, evaluate and compare the safety and efficacy of intramuscular PGF$_2$ a 125 mg and intravenous methergin 0.2 mg in the active management of third stage of labour

METHOD(S):
200 selected cases were divided in two groups of 100 each. In Group I, PGF$_2$ a 125 mg was given intramuscularly and in Group II, 0.2 mg methergin was given intravenously at the time of delivery of the anterior shoulder of the foetus. The duration of the third stage, amount of blood loss, side effects and complications, if any, were noted and analysed.

RESULTS:
The mean duration of the third stage of labour from the injection of the oxytocic to the expulsion of the placenta was significantly shorter in Group I (4.3±1.2 minutes) as compared to that in Group II (6.3±1.4 minutes) (P = 0.000). The mean blood loss was also significantly less in the study group (63.6±10.1 ml versus 83.6±14.1 ml, P = 0.000). The only side effects were nausea and vomiting in two women in Group I.

CONCLUSION(S):
Intramuscular PGF$_2$ a 125 mg is a better alternative to intravenous methergin 0.2 mg in the active management of third stage of labour.

INTRODUCTION
Although postpartum hemorrhage complicates only 5-10% of deliveries but it accounts for nearly 25% of the maternal deaths and is still considered one of the leading cause of maternal mortality in developing countries. Hence active management of of third stage of labour is the most important step towards reduction of maternal mortality. Use of an oxytocic has been recommended since long time. Methyl ergometrine given at the time of delivery of anterior shoulder has been reported to result in significant reduction in the blood loss of the third stage of labour.

Prostaglandins are the natural stimulants of the myometrial activity and have proven to be effective in induction of labour and abortion. Use of prostaglandins in the active
management of labour is an extension of their use in obstetrics, PGF$\alpha$, a synthetic derivative of prostaglandin, has an advantage that it can be given intramuscularly, is more potent and is longer acting than natural prostaglandin. The present study was undertaken to analyse the efficacy of PGF$\alpha$ in the active management of third stage of labour.

**METHODS**

Two hundred women with singleton pregnancy, spontaneous onset of labour at term and vertex presentation admitted in active phase of labour were included in the study. Those having hypertension, cardiac disease, renal disease, gastrointestinal disorders, respiratory disease, endocrinal problems, coagulation disorder and sensitivity to prostaglandin or methergin were excluded from the study.

They were randomly divided using random tables in two groups of 100 each. Group I received PGF$\alpha$ 125 μg intramuscularly and Group II received 0.2 mg of methergin intravenously at time of the delivery of the anterior shoulder. The interval between injection and expulsion of the placenta, amount of blood loss, third stage complications, side effects and need for second injection of additional drug were noted. Blood loss was estimated by blood and blood clots collected in the kidney tray and adding the difference in the weight of the drapes before use and after delivery. The data were analyzed.

**RESULTS**

There were 50 primiparas and 50 multiparas in each of the two groups. The two groups were well matched in terms of gravidity, parity and age (Table 1).

The mean duration of 1$^{st}$ stage of labour was 8.9±1.8 and 8.4 + 1.1 hours amongst primiparas in Group I and Group II respectively. It was 5.9± 1.2 and 6.1+1.0 hours amongst multiparas in Group I and Group II respectively. (Table 1).

The mean duration of the 2$^{nd}$ stage of labour was 40.3±9.3 minutes and 46.2+10.7 minutes amongst primiparas and 20.5 + 4.1 minutes and 20.4+3.7 minutes amongst multiparas in Group I and Group II respectively. (Table 1).

The mean duration of 3$^{rd}$ stage of labour was 4.1±1.0 minutes and 6.3 ±1.3 amongst primiparas in Group I and Group II respectively. It was 4.5±1.3 and 6.2±1.5 amongst multiparas in Group I and Group II respectively. Thus mean duration of third stage was significantly less in Group I as compared to that in Group II (4.3±1.2 vs 6.3±1.4 minutes; p=0.000) Table 1.

The mean amount of the blood loss was also significantly less in Group I as compared to that in Group II (63.6±10.1 vs 83.6±14.1 mL, p=0.000) Table 2.

In none of the women was the placenta retained in any of the groups. The additional dose of the drug was required in one case in the methergin group and none in prostaglandin group.

**Figure 2**

Table 2 - Amount of blood loss
The only side effects noted were nausea and vomiting in two cases in the prostaglandin group which were not severe enough to need energetic management.

**DISCUSSION**

Kerkes and Domokos recorded changes in the intraumbilical artery pressure with an open catheter and Hewlett Packard 8020 after treating the cases with PGF2α (n=6), ergometrine (n=3), physiological saline (n=4). They found a marked rise of 60 mm of Hg in the pressure and a sustained contracture response of the myometrium with PGF2α as compared to minimal response with ergometrine. They observed similar results after intra-myometrial injection of PGF2α during the caesarean section when a wave of contractions was seen starting from the site of the injection and spreading to the distal segment of the uterus. The sustained contracture superimposed with cyclical contractile uterine activity resulted in rapid separation and expulsion of the placenta and sustained contraction resulted in significant control of blood loss.

In the present study we also observed a significant reduction in the duration of the 3rd stage of labour in the PGF2α group as compared to that in methergin group. Similar observations were made by other authors as well (Table 3).

The mean blood loss was 63.6±10.1 ml in the prostaglandin group as compared to 83.6±14.1 ml in the methergin group. (P =0.000). (Table 3). Similar results were obtained by various other authors as well (Table 3).

Singh and Megh observed nearly 50% reduction in the mean blood loss using 250 µg of PGF2α in comparison to that of PGF2α with methergin. The side effects observed with prostaglandin were very minimal in the form of nausea and vomiting in two cases only. Ajaneyulu et al noted diarrhea as the most common side effect with vomiting in only 2% of the cases receiving prostaglandin while Singh and Megh observed vomiting as the main side effect in the prostaglandin treated group.

**CONCLUSION**

PGF2α 125 µg given intramuscularly is a safe and effective alternative to methergin for the active management of labour. It results in significant reduction in the blood loss which is so important in the anaemic women of our country.
