Vestibular Schwannoma Screening Guidelines: Change in our practise. An audit loop

H Prabhu, D Ingrams, M Clayton, M Kasaragod

INTRODUCTION

Vestibular Schwannoma is a benign tumour of the 8th cranial nerve, usually arising from the inferior division of the Vestibular nerve. It presents with wide range of symptoms such as asymmetrical sensorineural hearing loss, unilateral tinnitus, cranial nerve palsy, meniere’s symptom triad, and cerebellar compressing symptoms and on occasions as surprises.

Gadolinium enhanced MRI scans of internal auditory meatus is recognised as the current “gold standard” and cost effective investigation of choice for tumour detection, being able to detect tumours as small as 4mm in diameter [1] [2].

The falling costs of MRI compared to screening batteries have led to recommendation that it should be used as the sole investigation [2].

Northern Regional Guidelines were introduced by Northern and Yorkshire regional hospitals. These guidelines were followed and audit loop was conducted between 1994 and 1998, at the Sunderland Royal Hospital [3]. The out come of their audit was significant, and results published, which was comparable to other results.

OBJECTIVES

Aim of this audit was to follow set guidelines for requesting MRI scans in clinically suspected vestibular schwannoma patients. Royal Gwent Hospital in Newport is the busiest district general hospital in South Wales, serving a population of 600,000 populations.

STANDARD

Northern Regional Guidelines [3]

- Asymmetrical sensorineural hearing loss of 20dB or greater at two adjacent frequencies – even if there is another accountable cause
- Unilateral tinnitus – even if no asymmetry on the audiogram
- Meniere’s symptom triad
- Long- standing asymmetrical sensorineural hearing loss
- Asymmetric sensorineural loss less than 20dB at adjacent frequencies with accompanying neurological signs
- Sudden sensorineural hearing loss

Note: Claustrophobic patients will undergo ABR/ CT

METHODS

Primary audit was performed in June 2002. All MRI scans of Internal Auditory meatus were retrieved from radiology department for the period 1998 to 2001. The MRI reports
and patient notes were retrieved from the medical records. 
Primary audit was to compare our compliance with the 
Northern Regional Guidelines. 605 MRI scans were 
requested between 1998 and 2001. Requests were compared 
with the guidelines and outcome reported.

Northern Regional Guidelines were then introduced for 
requesting MRI scans in clinically suspected vestibular 
schwannoma patients. Guidelines were exhibited in all 
consultancy rooms and were discussed with the radiology 
team.

Re audit was conducted in May 2004. Total of 353 scans 
were requested between 2002 and 2004. These scan requests 
were retrieved from the radiology department and the 
department of medical records. Our compliance with the 
guidelines increased during this period.

RESULTS

During the period 1998 and 2001, 605 MRI scans of internal 
auditory meatus were requested, i.e. approximately 151 scan 
per year. The scans were requested by all grades of ENT 
surgeons, from consultants, registrars to senior house 
officers. 12 scan requests were positive for vestibular 
schwannoma. Our pick up rates for the period was 3.0% and 
this was comparative to other published results. The requests 
for these scans were all complying with the guidelines.

150 negative scans and the notes were reviewed. 120(80%) 
scan requests were within the guidelines (Table 1).

30(20%) scan requests did not comply with the guidelines 
(Table 2).

<td>Vertigo with family history of meniere’s Syndrome</td>
</tr>
</tbody>
</table>

After this arm of the audit, Northern regional guidelines 
were introduced to the department, and exhibited in all ENT 
consultancy rooms. This was discussed with the radiology 
team in the hospital.

Re audit was conducted in May 2004. 353 MRI scans of 
internal auditory meatus were requested between the period 
2002 and 2003, i.e. approximately 176 scans per year. 20 
patients who were claustrophobic did not have the scans and 
hence were excluded. 8 scan requests were positive for 
vestibular schwannoma. 4 scans were of a single patient who 
is followed up after stereo tactic radiotherapy treatment. 2 
scans were follow up patients after surgery. There were 2 
new cases during this period, with a pick up rate 1.0 % 
(incidence). The requests for these scans were complying 
with the guidelines.

202 negative scan requests and notes were retrieved. 
191(95%) requests complied with the guidelines (Table 3).

11(5%) requests did not comply with the guidelines (Table 
4).

DISCUSSION

A good effective audit is one in which the present practice is evaluated, compared with the standard, if any and then bringing about change in the practice if necessary. Re – evaluation of the practice is an important component of an effective audit.

This audit is hence a complete cycle of an audit loop.

Screening for vestibular schwannoma is a significant burden in the modern otology and radiology departments. Modern imaging techniques and surgical expertise allows early detection to be followed, where appropriate, by surgical treatment or any other modality with low morbidity and mortality. The rewards of early diagnosis and treatment of Vestibular schwannoma to the patient and community has been well documented in the literature [4] . This has increased the pressure on the otologist to diagnose the condition at an early stage. Litigation has been another issue in this modern medical practice.

Screening and protocols are two different entities. Screening guidelines are laid out statements which are flexible where as protocols are rigid statements.

There are various guidelines followed with regards to screening vestibular schwannoma patients. Differences in criteria’s of asymmetrical sensorineural hearing loss between the ears still persist. Age has been the criteria in few of the guidelines, the upper limit being 70 years [5]. Asymmetrical noise induced hearing loss has been another controversial topic to scan the patient [6]. As mentioned earlier guidelines are flexible when put into practice.

Northern regional guidelines were introduced in the Northern regional hospitals 1995. The guidelines were followed, re audited and the findings published, hence taken as a standard in our practice.

Northern regional guidelines for requesting the scans were followed over 2 years time. Our previous requests were compared to these guidelines and reported.

Number of inappropriate scan requests reduced from 20% to 5% between the audit periods 2002 and 2004. The number of scans requests increased from 151 per year to 176 per year, which is noted in other similar published studies. The pick up rates (number of new cases) has reduced from 2% to 1% over this audit period. The question to be asked is to whether all of the possible patients are being screened in view of the decreased pick up rates. A further audit in 2 years would possibly reveal any missed cases and also our compliance with the guidelines.
