Citation

Abstract
The aim of our physical anthropometric study was to determine sex (male/female) by foot measurements. Two hundred and fifty students (125 males and 125 females) of the age above 18 years were examined in the year 2005. The average foot length was found to be about 3cm greater in males as compared to females and the average foot breadth of males was about 1cm longer than females. The foot index was calculated and has been used for the determination of sex. To conclude, the foot index more than 37 is suggestive of female and less than 37 is that of male.

INTRODUCTION
Identification is often required in medico-legal practice. The problem mainly arises when the body is recovered in advanced stage of decomposition, mutilated state and skeletonized state. Sometimes, fragments of soft tissues are found disposed off in the open, in ditches, or rubbish dumps, etc. and this material is brought to forensic pathologist for examination.

Sex determination is a vital part of the analysis of human remains. Lots of researches are going on for assessing stature, sex, race, etc from anthropometric measurements of different parts of the body for identification purpose. In the present study, attempt has been made to find out co-relation of foot measurements with the sex (male/female).

METHODOLOGY
The study was conducted in the Department of Forensic Medicine & Toxicology, SSR Medical College, Mauritius in the year 2005 with collaboration of the Department of Anatomy. The material consists of 250 young and healthy students (125 males and 125 females) in the age group of 18-30 years. In this study, the sample included only the students above the age of 18 years. Above this age, most people attain their maximum growth and therefore their maximum foot length and breadth.

The foot length was measured as a straight distance between the most posterior projecting point of heel and the most anterior projecting point (the end of great toe or second toe) when placed on flat surface. This measurement excluded any nail extending over the end of the toe. The breadth of foot was measured as straight distance from the most medially placed point on the head of 1\textsuperscript{st} metatarsal to the most laterally placed point located on the head of 5\textsuperscript{th} metatarsal.

The apparatus used for this study were osteometric board and measuring tape.

Sex determination is a vital part of the analysis of human remains. Lots of researches are going on for assessing stature, sex, race, etc from anthropometric measurements of different parts of the body for identification purpose. In the present study, attempt has been made to find out co-relation of foot measurements with the sex (male/female).

RESULTS
Foot length: In males, the right foot length varied from 23.30 cm to 29.00 cm (mean 26.17 & SD 1.05) and left foot length varied from 23.10 cm to 29.10 cm (mean 26.14 & SD 1.06). In females, the right foot length varied from 21.10cm to 26.30cm (mean 23.33 & SD 1.08) and left foot length varied from 21.20cm to 26.30cm (mean 23.28 & SD 1.09). (Table 1)

Foot breadth: In males, the right foot breadth varied from
8.00 cm to 10.80 cm (mean 9.63 & SD 0.54) and left foot breadth varied from 7.90 cm to 11.10 cm (mean 9.62 & SD 0.54). In females, the right foot breadth varied from 7.50 cm to 10.00 cm (mean 8.74 & SD 0.50) and left foot breadth varied from 7.50 cm to 10.30 cm (mean 8.75 & SD 0.52). (Table 2)

Foot index: In males, the foot index ranged from 36.50 (18-19 yrs) to 36.97 (20-21 yrs). In females, it ranged from 37.04 (18-19 yrs) to 37.93 (20-21 yrs). (Table 3 & 4)

DISCUSSION

Many physical anthropometric studies show the gender difference.\(^2\), \(^3\), \(^4\) The average male is ten centimeters taller than the average female and this difference will also be translated in an overall trend that males will have greater foot length as compared to females.\(^5\)

In our study, males had an average foot length about 3 cm greater than the females’ foot length. The foot breadth was about 1 cm greater in males as compared to females. In all age groups, the foot index in females was found to be more than 37, and in males, it was less than 37. Therefore, this value i.e. 37 can be used as a deviation point for the determination of sex. Thus the present study indicates a positive correlation between an individual’s foot measurements and gender, which is consistent with the study conducted by Tyagi et al.\(^6\) Thus sex can be determined by foot index with fair accuracy. Further researches are needed in this field.

ACKNOWLEDGEMENT

We thank medical students for their cooperation in the conduction of this study.
