Abstract
I describe a simple maneuver to place the skin incision for the inguinal hernia repair. All the open operative techniques for inguinal hernia repair use a transversely oriented slight curvilinear skin incision of 6-8cm positioned one to two fingerbreadths above the inguinal ligament¹. Classically the incision is made between the anterior superior iliac spine and the pubic tubercle². Technically it may be difficult to identify these two landmarks. Hence, the exposure can be very difficult especially in obese patients³.

TECHNIQUE
Simply, the external inguinal ring can be identified through the skin by the external ring test which was previously used to differentiate between the diagnosis of the direct and indirect hernia, Fig. 1. The examining finger is introduced in the inguinal canal to delineate it and the incision is placed directly on the inguinal canal starting from the site of the external inguinal ring, Fig. 2. Dissecting the subcutaneous tissues directly goes down to the external oblique fibers, Fig. 3.
